Foreign direct investment and international trade in BIMSTEC: panel causality analysis

Mohd Nayyer Rahman^a and Harpal S. Grewal^b

^aDepartment of Business Management, Integral University, Lucknow, India; ^bSchool of Business, Claflin University, Orangeburg, SC, USA

ABSTRACT

Economic engagement and disengagement are part and parcel of political economy and geopolitical concerns. The recent non-participation of India in the South Asian Association for Regional Cooperation summit has proved fatal. This has resulted in the shift of attention of the major Asian countries towards The Bay of Bengal Initiative for Multi-Sectoral Technical and Economic Cooperation (BIMSTEC) region for world trade and foreign direct investment (FDI). The present study is an attempt to empirically identify the causality between variables of FDI and world trade across panel data for BIMSTEC countries. This is an attempt to search for further causality.

KEYWORDS

BIMSTEC; causality; FDI; world trade

1. Introduction

Regional economic integration starts with initial international trade between countries commonly known as bilateral trade. Though it is to be noted that trade between two countries is not bilateral unless there is pre-determined and conscious intention between the governments of the respective countries. As agreements between countries become more formal, it takes a particular nomenclature. The same is the story of the South Asian Association for Regional Cooperation (SAARC), as an association of South Asian nations. In 2016, the rivalry between India and Pakistan bolstered and eventually India backed off from attending the SAARC summit. Afghanistan supported the move of India, others gave a diplomatic response. In the aftermath of such incident, there is an argument going both in academic circles and foreign affairs circles, that BIMSTEC must be given more importance as SAARC has collapsed. This particular notion has become popular and has also been seriously taken by the global friends of India or the opponents of Pakistan. The present study is an endeavour to understand Foreign Direct Investment (FDI) and world trade in the BIMSTEC region due to its growing importance and utility. Causality analysis will be conducted on the basis of FDI and world trade. [Section 2](#) deals with the review of literature in general as well as on specific issues related to FDI and international trade. [Section 3](#) and [Section 4](#) are focussed on the conceptual framework and econometric models and estimation methods. [Section 5](#) discusses the sources of data. Results and conclusion are elucidated under [Section 6](#) and [Section 7](#).

2. Literature review

At the outset, it is befitting to state that almost no studies have conducted an inquiry about causality evidence with respect to macroeconomic variables among BIMSTEC countries. The Bay of Bengal Initiative for Multi-Sectoral Technical and Economic Cooperation (BIMSTEC) has a long history since its inception in 1997 when it was known as BIM-EC. Later on, when it was joined by Thailand it was extended to BIMSTEC. The member countries have regularly met with each other in the ministerial meeting and have bolstered their relationship both qualitatively and quantitatively. However, it has recently got much attention due to the failed summit of SAARC in 2016. Researchers have discussed the free trade agreement of BIMSTEC but have failed to come up with any causality study. Relatively more work has been conducted in the sphere of BIMSTEC-Japan relationship and agreements. Yahaya (2005) has highlighted the inability of SAARC to promote inter-regional trade and has concluded that

BIMSTEC will emerge even in the presence of a hostile relationship between India and Pakistan. ASEAN will be another group interested in BIMSTEC as members are mutually inclusive. The importance of BIMSTEC for India and Thailand has also been highlighted by researchers working in the area of regional trade agreements. Specifically, the view is that BIMSTEC is a progressive agreement which benefits the Asian region (Kumar, 2007). The interest and growing investment of Japan into BIMSTEC region have been highlighted by researchers as an indicator of growing potential of the BIMSTEC region (Banik & Bhaumik, 2005). The relationship between BIMSTEC and Japan with respect to FDI and world trade will also benefit the region. It would be justified to draw the inference that BIMSTEC region may surpass the growth rate and low conflicts of ASEAN region (Bhattacharyaa & Bhattacharyaa, 2007).

3. Conceptual framework

An inquiry into the bi-directional relationship between any two economic variables requires developing an understanding of conceptual issues before the model is specified. Apart from using descriptive statistics for a casual comparison, the study has an exclusive objective of building a causal relationship between FDI and world trade for BIMSTEC region. The first and foremost important question is to quantify world trade for BIMSTEC region. Common sense generates two proxies that are; the contribution of BIMSTEC region in net exports or contribution of BIMSTEC region in exports. However, the paper argues that flow of trade is reflected in both exports and imports and therefore both should be included under proxy for world trade. Thus, in this view, benefit to capture the objective of the present endeavour. Therefore, the selected proxy for world trade is exports and imports of BIMSTEC region. The other variable is FDI and the argument is strong for a comparison of concepts that are of similar nature. This transforms into the meaning that FDI Inflows are a primary concern for the region. BIMSTEC region is formed with an objective of integrating into the world trade and in turn get long-term capital benefits. These capital benefits are in the form of FDI Inflows whose main attracting factors for the host economy/region remains technology transfer, knowledge transfer etc. Eventually, the two selected variables are FDI Inflows and total trade (Exports and Imports) of BIMSTEC region. The theoretical relationship at the first stage can be verified with the help of correlation followed by regression but both may be spurious in the absence of a universally accepted theory. Thanks to modelling that common sense and plausibility suffice for the pre-requisite of an economic theory.

It is to be noted that the data used in the study is a panel data spread at a time from 1980 to 2015. The panel is a balanced panel. Further details about the data used would be explored in Section 5 (The Data). In order to test for the presence of causality between the two variables, panel data causality will be employed. The approach to be followed remains confined to the use of stable and necessary conditions for running the Panel unit root testing followed by identifying the number of lags and then developing VAR and testing for necessary and stable conditions such as AR roots graph. There is no need of checking for the problem of serial correlation as the data used is panel data. Badi H. Baltagi (1995) wrote about the benefits of panel data 'Panel data ... more informative data, more variability, less collinearity among variables, more degrees of freedom and more efficiency'. Thus, eventually, the study is a search for identifying causality between FDI and world trade for BIMSTEC region. In order to approach panel granger causality (1969), the first step is to identify the order of integration for the series. In other words, the needful information is about stationarity of the data. Out of the several available panel unit root test, the present study employs two tests with opposite null hypothesis. This is in order to bolster the results. Kocenda & Cerny (2014) has specifically argued in support of such alternative unit root tests. The selected panel unit root test are Common root - Levin, Lin, Chu (2002) and Hadri (2000). While in the first test, the null hypothesis is 'Unit Root', in the latter the null is 'No unit root'. The summary of both the test used is as presented in Table 1.

Table 1. Properties of panel unit root tests.

Test	Null	Alternative	Possible deterministic component	Autocorrelation correction method
Levin, Lin, and Chu	Unit root	No unit root	None, F, T	Lags
Hadri	No unit root	Unit root	F, T	Kernel

None: no exogenous variables; F: fixed effect; T: individual effect and individual trend.

Source: Prepared by researcher through Eviews manual; http://www.eviews.com/help/helpintro.html#page/content/advtimeserPanel_Unit_Root_Testing.html.

The model for panel unit root is as follows:

$$Y_{it} = \rho_i Y_{it-1} + X_{it}\delta_i + \varepsilon_{it}$$

where, $i = 1, 2, \dots, N$ cross section series to be observed over periods $t = 1, 2, \dots, T_i$

X_{it} is exogeneous variable.

ε_{it} represent errors that are mutually independent idiosyncratic disturbance ρ_i represents autocorrelation coefficients,

Levin et al. (2002) test derives estimate of α from proxies for ΔY_{it} and Y_{it} standardised and free of autocorrelation and deterministic components. The t statistic is calculated in the following manner:

$$t_\alpha = \frac{t_\alpha - (NT)S_{N^0-2}se(\hat{\alpha})\mu_{m^T}}{\sigma_{m^T}} \rightarrow N(0, 1)$$

The alternate panel unit root test used is Hadri (2000), which works in the manner of KPSS test wherein the null hypothesis is of stationarity. It is based on the residuals of OLS and on the basis of residuals LM test statistic is calculated which is as follows:

$$LM_1 = \frac{1}{N} \left\{ \sum_{i=1}^N \left(\frac{\sum S_i(t)^2}{T^2} \right) / f_0 \right\}$$

As a prerequisite for developing Vector Auto Regression (VAR) model, panel cointegration will be checked. Kao Residual Cointegration Test is used for such an objective. The lag length will be selected by the criteria of minimising the SIC value to be found with the VAR output. Finally, the Granger Causality (1969) will be identified. The methodology for finding causality will be that of Toda and Yamamoto (1995) approach where data is in levels and the adjustment is done at the time of estimating VAR by differencing the variables as Exogenous variables.

4. Econometric model and estimation methods

In order to decide the causality or impact between the relevant variables Toda and Yamamoto (1995) non-causality approach would be followed. This would be along with the application of the direct approach without the difference stationary process (DSP) and would be using the data in levels. However, it does not mean that order of integration of the series would not be checked. Variables used in the study are described in Appendix 1. In the case of three variables, simple X , and Y Granger causes Z if Z can be better predicted using the histories of X , Y , and Z than it can by using the history of Z alone. The absence/presence of panel Granger causality (1969) will be tested using the following set of the equations:

EXPT, FDII, and IMPT

$$EXPT_t = a_0 + a_1EXPT_{t-1} + \dots + a_pEXPT_{t-p} + b_1FDII_{t-1} + \dots + b_pFDII_{t-p} + c_1IMPT_{t-1} + \dots + c_pIMPT_{t-p} + \mu_t \quad (1.1)$$

$$FDII_t = a_0 + a_1FDII_{t-1} + \dots + a_pFDII_{t-p} + b_1EXPT_{t-1} + \dots + b_pEXPT_{t-p} + c_1IMPT_{t-1} + \dots + c_pIMPT_{t-p} + \mu_t \quad (1.2)$$

$$IMPT_t = a_0 + a_1IMPT_{t-1} + \dots + a_pIMPT_{t-p} + b_1FDII_{t-1} + \dots + b_pFDII_{t-p} + c_1EXPT_{t-1} + \dots + c_pEXPT_{t-p} + \mu_t \quad (1.3)$$

The hypotheses for Equation 1.1 are as follows:

H_{01} : For the panel of BIMSTEC, FDI inflows and imports does not Granger cause Exports.

H_{A1} : For the panel of BIMSTEC, FDI inflows and imports Granger cause Exports.

Maintained/mathematical hypotheses for the same are as follows:

$$H_{01} : b_1 = b_2 = \dots = b_p = 0$$

$$H_{A1} : b_1 \neq b_2 \neq \dots \neq b_p \neq 0$$

The hypotheses for Equation 1.2 are as follows:

H_{02} : For the panel of BIMSTEC, imports and exports does not Granger cause FDI inflows.

H_{A2} : For the panel of BIMSTEC, imports and exports Granger cause FDI inflows.

Maintained/mathematical hypotheses for the same are as follows:

$$H_{02} : d_1 = d_2 = \dots = d_p = 0$$

$$H_{A2} : d_1 \neq d_2 \neq \dots \neq d_p \neq 0$$

The hypotheses for Equation 1.3 are as follows:

H_{03} : For the panel of BIMSTEC, FDI inflows and exports does not Granger cause imports.

H_{A3} : For the panel of BIMSTEC, FDI inflows and exports Granger cause imports.

Maintained/Mathematical hypotheses for the same are as follows:

$$H_{03} : f_1 = f_2 = \dots = f_p = 0$$

$$H_{A3} : f_1 \neq f_2 \neq \dots \neq f_p \neq 0$$

For estimating the VAR model, determination of a number of lags p would be done on minimising the Akaike (1974) Information Criteria.

5. Data and results

The study used three macroeconomic variables expressed in US million dollars and the data is taken from UNCTAD database. The three variables are Foreign Direct Investment Inflows (FDII), Exports (EXPT), and Imports (IMPT). The time period for data is from 1980 to 2015. The UNCTAD database has not been updated for 2016 with respect to one or more variables in the study. Thus in order to have a symmetry, data until 2015 is used for inferences. The data set is referred to Appendix 2.

The analysis for the panel study has been initiated with step one as identification of the order of integration of the series. For this panel unit root tests are used with opposite null hypothesis. The output of the unit root testing is presented in Table 2.

Recall that the null hypothesis for Levin et al. (2002) is 'unit root' while for Hadri (2000) it is 'no unit root'. The results of both the alternative panel unit root tests are same and thus bolster the results. According to it all the three series, EXPT, FDII and IMPT are non-stationary at level but stationary at first difference. Thus, the correct order of integration for all three series is 1, i.e. I(1). This information will be further utilised while estimating VAR and subsequently checking for Granger causality (1969). As the Toda and Yamamoto (1995) approach is followed, the study does not difference the data and use the level data for further analysis. Once this is over, Panel cointegration is checked and the output is presented in Table 3.

Table 2. Results of panel unit root testing.

Series	Order of integration	Levin, Lin, Chu Prob.	Hadri Prob.
EXPT	0	0.9996	0.0000
	1	0.0000 ^a	0.1851 ^a
FDII	0	0.2693	0.0000
	1	0.0000 ^a	0.9456 ^a
IMPT	0	0.9945	0.0000
	1	0.0001 ^a	0.1626 ^a

2	H ₀₂ : For the panel of BIMSTEC, Imports and Exports does not Granger cause FDI Inflows.	0.0000, 0.0000	Reject
3	H ₀₃ : For the panel of BIMSTEC, FDI Inflows and Exports does not Granger cause Imports.	0.0000, 0.0000	Reject

Source: Prepared by the researcher.

The null hypothesis for the Kao panel cointegration is 'There is no cointegration between series EXPT, FDII, and IMPT for the panel of BIMSTEC'. As the probability value is more than 0.05 (0.4941), the null hypothesis of no cointegration is accepted, this gives a push for moving forward with estimating the VAR without any unresolved issues. Unrestricted VAR is setup for the three variables and in that hit and trial method is used up to five lags in order to minimise the SIC criteria. Following Miyakoshi and Tsukuda (2004) and Atukeren (2007), the SIC value is minimised at lag 5 and therefore lag 5 is selected as the appropriate lag. The lag result is presented in Table 4.

Eventually, VAR model has estimated with five lags and the data is in levels. In order to integrate the precise information by panel unit test, the differencing is stimulated with the help of Toda and Yamamoto (1995) approach. The variables with differencing are assumed to be under exogenous variables. This means that the three variables are specified in the following functional form:

$$\text{EXPT}(-1), \text{IMPT}(-1) \quad \text{and} \quad \text{FDII}(-1).$$

This suffices for differencing and as a necessary and sufficient condition to go for Block Exogeneity Granger causality. The output of panel granger causality is shown in Tables 5, 6 and 7.

On the basis of Tables 5, 6 and 7, the rejection and acceptance of hypothesis is shown in Table 8.

6. Conclusions

In the end, it would be justified to state that BIMSTEC region holds great potential and opportunity for world trade. The panel causality analysis of the FDI and world trade for the region suggests the existence of causality

evidence for the seven member countries. The findings of the study suggest a causality running from FDI inflows and imports to exports for the region as well as from imports and exports to FDI Inflows. Similarly, there is a causal evidence from FDI inflows and exports towards imports in the panel for the region for the sample period. The casual evidence is the important finding for policymakers as well as academicians as a scientific evidence opposed to economic intuition or casual relationships.

Disclosure statement

No potential conflict of interest was reported by the authors.
